

## Chapter 1

### 1.1 Divisibility

By Natural numbers we mean the numbers 1, 2, 3, .....

Integers are Natural numbers, 0 and the negative numbers ...-3, -2, -1. The set of integers

will be denoted by  $Z$  such that

$$Z = \{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}.$$

#### **Definition 1.1.1**

If  $a$  and  $b$  are Integers with  $a \neq 0$ , we say that  $a$  divides  $b$  if there is an integer  $c$  such that  $b=ac$ .

If  $a$  divides  $b$ , then  $a$  is a divisor or factor of  $b$ .

If  $a$  divides  $b$  we write  $a | b$ , if  $a$  doesn't divide  $b$  then  $a \nmid b$ .

#### **Example (1):**

The following illustrate the concept of divisibility of integers :

$$13 | 182, -5 | 30, 6 \nmid 44, 7 \nmid 50 \text{ and } 17 | 0.$$

#### **Example (2):**

The divisors of 6 are  $\pm 1, \pm 2, \pm 3, \pm 6$ .

The divisors of 17 are  $\pm 1, \pm 17$ .

The divisors of 100 are  $\pm 1, \pm 2, \pm 4, \pm 5, \pm 10, \pm 20, \pm 25, \pm 50$  and  $\pm 100$ .

#### **Note that:**

Every non-zero integer is a divisor of 0 and 1 is a divisor of every integer or equivalently every integer is a multiple of 1.

### 1.3 The Euclidean Algorithm

The gcd of two integers can be found by listing all +ve divisors and picking out the largest one common to each, but this is not suitable for large numbers.

A more efficient process involving repeated application of the division algorithm goes by the name of

Euclidean Algorithm. The E.A. may be described as follows :

Let  $a, b$  be two integers whose gcd is desired, we can find unique integers  $q_1, r_1$  such that

$$a = bq_1 + r_1 \quad 0 \leq r_1 < b$$

if  $r_1 \neq 0$  we divide  $b$  by  $r_1$  so

$$b = r_1 q_2 + r_2 \quad 0 \leq r_2 < r_1.$$

if  $r_2 \neq 0$  we divide  $r_1$  by  $r_2$  so

$$r_1 = r_2 q_3 + r_3 \quad 0 \leq r_3 < r_2.$$

Similarly if  $r_3 \neq 0$

$$r_2 = r_3 q_4 + r_4 \quad 0 \leq r_4 < r_3$$

.

.

.

$$r_{k-2} = r_{k-1} q_k + r_k \quad 0 < r_k < r_{k-1}$$

$$r_{k-1} = r_k q_{k+1} + 0 \quad r_{k+1} = 0.$$

By the repeated application of Theorem 1.2.5, we can show that  $r_k$ , the last non-zero remainder which appears in this manner is equal to  $(a, b)$ ,

$$3(-6) + 6(6) = 18$$

$$3(10) + 6(-2) = 18.$$

where as the equation  $2x + 10y = 17$  which has no solution .

so its reasonable to ask about the conditions under which a

solution is possible . The answer is given by the following theorem .

**Theorem 1.5.2:**

Let  $a, b$  be integers with  $d = (a, b)$  . The equation  $ax + by = c$  has no integral solution if  $d \nmid c$ .

If  $d \mid c$  then there are infinitely many integral solutions . Moreover , if  $x = x_0, y = y_0$

is a particular solution of the equation , then all solutions are given by

$x = x_0 + (b/d)n, y = y_0 - (a/d)n$ , where  $n$  is an integer .

**Proof :**

Assume that  $x$  and  $y$  are integers such that  $ax + by = c$  . Then since  $d \mid a$  and  $d \mid b$  so  $d \mid c$  .

Hence if  $d \nmid c$  , there are no integral solutions of the equation.

Assume that  $d \mid c$ . Since  $(a,b)=d \exists s,t \in \mathbb{Z}$ , such that

$$d = as + bt \dots\dots(*)$$

Since  $d \mid c$  there is  $e \in \mathbb{Z}$  such that  $de = c$ .

Multiply both sides of (\*) by  $e$  we get

$$c = de = (as + bt) e = a(se) + b(te).$$

Let  $k = 4n + 1$ ,  $k' = 4m + 1$   
 Then  $kk' = (4n + 1)(4m + 1)$   
 $= 16mn + 4n + 4m + 1$   
 $= 4(4mn + n + m) + 1$   
 $= 4L + 1$ , where  $L = 4mn + n + m$ .

Which is of the desired form.

**Theorem 2.2.5:**

There is an infinite number of primes of the form  $4n + 3$ .

**Proof :**

In anticipation of a contradiction, let us assume that there exist only finitely many primes of the form  $4n+3$ , call them  $q_1, q_2, \dots, q_s$ . Consider the positive integer

$$N = 4 q_1 q_2 \dots q_s - 1 = 4 (q_1 q_2 \dots q_s - 1) + 3,$$

and let  $N = r_1 r_2 \dots r_t$  be its prime factorization.

Because  $N$  is an odd integer, we have  $r_k \neq 2$  for all  $k$ , so that each  $r_k$  is either of the form  $4n+1$  or  $4n+3$ . By the lemma above the product of any number of primes of the form  $4n + 1$  is again an integer in this type for  $N$  take the form  $4n+3$  as its clearly dose,

$N$  must contain at least one prime factor  $r_i$  of the form  $4n+3$ . But  $r_i$  cannot be found among the listing  $q_1, q_2, \dots, q_s$ , for this would lead to a contradiction that  $r_i | 1$ .

The only possible conclusion is that there are infinitely many primes of the form  $4n+3$ .

**Theorem 2.2.6: (Dirichlet)**

If  $a$  and  $b$  are relatively prime positive integers i.e  $(a, b) = 1$ , then the arithmetic progression

$a, a + b, a + 2b, a + 3b$   
 contains infinitely many primes.

**Example(6):**

$(3, 4) = 1$ , therefore the arithmetic progression is

$3, 3 + 4, 3 + 2(4), 3 + 3(4), 3 + 4(4), 3 + 5(4), \dots$

i.e, the arithmetic progression is  $3, 7, 11, 15, 19, 23, \dots$

contains infinitely many primes all of them are of the form  $4n + 3$ .

Similarly  $(1, 4) = 1$  therefore the arithmetic progression is :

$1, 1 + (4), 1 + 2(4), 1 + 3(4), 1 + 4(4), 1 + 5(4), \dots$  ,i.e.  $1, 5, 9, 13, 17, 21, \dots$

contains infinite number of primes of the form  $4n + 1$ .

**Theorem 2.2.7:**

No Arithmetic progression of the form  $a, a + b, a + 2b, \dots$ , contains only primes.

**Proof :**

Let  $a + nb = p$  where  $p$  is a prime.

If we put  $n_k = n + kp$ ,  $k = 1, 2, 3, \dots$ , then the  $n_k^{\text{th}}$  term in the progression is  
 $a + n_k b = a + (n + kp) b$

$$\begin{aligned}\varphi(720) &= \varphi(2^4 \cdot 3^2 \cdot 5) = 720\left(1 - \frac{1}{2}\right)\left(1 - \frac{1}{3}\right)\left(1 - \frac{1}{5}\right) = 192 \\ \varphi(450) &= \varphi(2 \cdot 3^2 \cdot 5^2) = 450\left(1 - \frac{1}{2}\right)\left(1 - \frac{1}{3}\right)\left(1 - \frac{1}{5}\right) = 120\end{aligned}$$

**Example (22)**

If  $f$  is an arithmetic function, then

$$\sum_{d|12} f(d) = f(1) + f(2) + f(3) + f(4) + f(6) + f(12)$$

for example

$$\begin{aligned}\sum_{d|12} d^2 &= 1^2 + 2^2 + 3^2 + 4^2 + 6^2 + 12^2 \\ &= 1 + 4 + 9 + 16 + 36 + 144 = 210.\end{aligned}$$

The following result which states that  $n$  is the sum of values of the phi-function at all the positive divisors of  $n$  will be useful.

**Theorem 4.3.13**

Let  $n$  be positive integer, then  $\sum_{d|n} \varphi(d) = n$ .

Let  $n = p^\alpha$ , then the divisor of  $p^\alpha$  are  $1, p, p^2, \dots, p^\alpha$ . Therefore

$$\begin{aligned}\sum_{d|n} \varphi(d) &= \varphi(1) + \varphi(p) + \varphi(p^2) + \dots + \varphi(p^\alpha) \\ &= 1 + p - 1 + p^2 - p + \dots + p^\alpha - p^{\alpha-1} \\ &= p^\alpha = n.\end{aligned}$$

Hence the result is true for  $n = p^\alpha$ .
